

PRODUCT MATTERS 6.0 · WEEK 3 · PROTOTYPING SUBMISSION

TrustFix

From Wireframes to a Working Model

A clickable, AI-assisted prototype of TrustFix's core customer and service-professional flows - built on top of the Week 2 problem definition, personas, and MVP scope.

By Chhavi Tanwar

A wireframe hides decisions. Building doesn't.

The Week 2 deck answered what TrustFix should do. Wiring the same flows into a tap-through prototype forced answers to how it actually behaves - sequencing of OTP and payment, what happens on cancellation, and which screens a low-literacy professional genuinely needs. Nothing in the MVP scope or personas changed; several interaction details underneath them got sharper.

Held constant from Week 2

- ✓ Personas: Riya Sharma (Anxious Customer) & Rajesh Kumar (Stressed Professional)
- ✓ The Three Pillars: Predictable Pricing, Verified Credential Layer, Low-Friction Bridge
- ✓ MVP scope: standardized pricing, OTP verification, one-tap acceptance
- ✓ Cold-start GTM: single city, two categories at launch

2

End-to-end flows prototyped - Customer booking and Professional job acceptance

15

Screens wired into one clickable prototype (8 customer + 7 professional)

5

Concrete product decisions resolved that Week 2 had left implicit

Vibe-coded, not hand-built

Claude (AI-assisted / vibe coding)

Directed an AI coding assistant to translate the Week 2 wireframes and User Journey directly into a working interactive prototype - describing each screen's intent rather than writing markup by hand.

Single-file HTML / CSS / JS prototype

No build pipeline. One self-contained file, viewable in any browser or hosted instantly on a static host - chosen for zero setup time given no dedicated engineering support.

Two toggleable app frames

A phone-frame mock for the Customer app and a separate one for the Professional app, switchable from a single tab - so both sides of the marketplace live in one shareable prototype.

Built-in rationale panel

Every screen ships with an inline 'why this screen exists' note tracing back to a Week 2 persona, pillar, or MVP feature - forcing traceability instead of assuming it.

Customer flow: Riya books a service

Why these 8 screens

This is the assignment's minimum bar: "service discovery and booking on the customer side." Every screen maps to a step in Week 2's User Journey - Discovery → Matching → Execution → Settlement - with OTP verification and binary rating carried over exactly as specified, not reinterpreted.

Deliberately left out: multi-item cart / bundling several services in one booking

Early prototyping showed it added choice complexity that fights the "predictable, no-friction" pillar - cut to keep depth on one job at a time, as the constraints require.

Professional flow: Rajesh accepts a job

Why these 7 screens

Covers the assignment's other required minimum: "job acceptance / availability management on the service-professional side." Every screen was kept to large tap targets and near-zero reading, in line with Rajesh's low-digital-literacy persona constraint - reusing the same map and OTP components the customer app uses.

Deliberately left out: in-app real-time chat between customer and professional

Already scoped "No - High Complexity" in the Week 2 Feature Deep Dive, with call-masking as the fallback. The prototype keeps a call icon only, on purpose.

What we chose not to prototype, and why

Not prototyped	Reasoning
Multi-item cart / bundled bookings	Adds choice complexity that undercuts the predictable, one-tap booking promise
In-app real-time chat	Already cut in the Week 2 Feature Deep Dive as high complexity; call-masking is the fallback
AI-driven dynamic surge pricing	Also cut in Week 2; static rate cards suffice for a single-city launch
Mid-job parts/material unavailability	A real gap, but resolving it needs a policy decision, not just a screen
Dispute / refund flow after a thumbs-down	Rating capture is in scope; the resolution workflow behind it is a future task

Gaps a wireframe let us avoid

Unlaunched categories (Plumbing, Cleaning) had no visual state

Added an explicit disabled state instead of hiding them - sets correct expectations at launch

Payment and completion-OTP order was ambiguous

Sequenced explicitly: OTP confirms work is done before the charge fires, never simultaneous

Cancellation after the professional is en route was undefined

Flagged as an open policy decision - a cancellation fee rule is needed before launch

Professional home screen carried an unnecessary job-history tab

Cut it - today's earnings and Trust Score are the only two numbers Rajesh needs at a glance

Payout trigger vs. "job marked complete" was one vague step

Split into two explicit events: professional shows completion code → customer confirms → payout releases

Same scope, sharper rules underneath

No Week 2 MVP feature was added or removed. Three were refined with an explicit sequencing or state rule the wireframe hadn't specified.

MVP Feature	Status	What changed
Upfront Standardized Pricing	Unchanged	Shown before booking; disabled state added for unlaunched categories
OTP-Verified Job Start & End	Refined	Explicit rule: completion OTP must be entered before payment is charged
One-Tap Job Acceptance Flow	Unchanged	Distance, customer rating, and payout shown together on a single screen
Digital Job Card + Before/After Photos	Refined	Defined as the sole record-keeping surface; parts-unavailable case deferred
Payout release	Refined	Split into two explicit events: code shown → customer confirms → payout

What the prototype confirms and what it flags

North Star Metric - unchanged

Completed, OTP-verified bookings per week, per city

Supporting signals reinforced by the prototype:

Booking-to-confirmed-match rate (tests single-match design, not a browsable list)

Arrival-OTP share rate (proxy for customer trust in the safety flow)

Rebooking rate on the "Book again" shortcut (proxy for repeat trust)

Professional accept-rate within 45 seconds (tests one-tap simplicity)

New risks surfaced while prototyping

No cancellation-fee policy

Customers can cancel post-match with zero cost today - needs a rule before pilot launch

No mid-job parts-unavailable flow

Professional has no defined path if a job can't be finished as booked

OTP-sharing friction for first-time users

Two separate 4-digit codes per job may confuse first-time, low-literacy users - needs usability testing

Single-match design has no visible fallback

If the nearest verified professional doesn't respond, the customer currently sees no re-match state

“Making Trust Measurable.”

The prototype doesn't change what TrustFix promises Riya and Rajesh - it proves the promise can be tapped through, screen by screen, end to end.
